1 Statement

China Satellite Navigation Office is responsible for the preparation, revision, distribution, and retention of BeiDou Navigation Satellite System Signal In Space Interface Control Document (hereinafter referred to as ICD), and reserves the right for final explanation of this ICD.

2 Scope

The construction and development of BeiDou Navigation Satellite System (BDS) is divided into three phases: BDS-1, BDS-2 and BDS-3 in sequence.

This document is a upgraded version of *BeiDou Navigation Satellite System Signal In Space Interface Control Document Open Service Signal (Version 2.1)*, and mainly defines the characteristics of the open service signal B1I transmitted from the BDS space segment to the BDS user segment. The B1I signal is transmitted by the BDS-2 and BDS-3 satellites including Medium Earth Orbit (MEO) satellites, Inclined GeoSynchronous Orbit (IGSO) satellites and Geostationary Earth Orbit (GEO) satellites for providing open services.

Note: The B2I signal is transmitted by all the BDS-2 satellites and also provides open services, which will be replaced by the B2a signal on the BDS-3 satellites. For more information about the B2I signal, please refer to *BeiDou Navigation Satellite System Signal In Space Interface Control Document Open Service Signal (Version 2.1)*.

3 BDS Overview

3.1 Space Constellation

The nominal space constellation of BDS-2 consists of 5 GEO satellites, 5 IGSO satellites and 4 MEO satellites. According to actual situation, spare
satellites may be deployed in orbit. The GEO satellites operate in orbit at an altitude of 35,786 kilometers and located at 58.75°E, 80°E, 110.5°E, 140°E, and 160°E respectively. The IGSO satellites operate in orbit at an altitude of 35,786 kilometers and an inclination of the orbital planes of 55 degrees with reference to the equatorial plane. The MEO satellites operate in orbit at an altitude of 21,528 kilometers and an inclination of the orbital planes of 55 degrees with reference to the equatorial plane.

The nominal space constellation of BDS-3 consists of 3 GEO satellites, 3 IGSO satellites, and 24 MEO satellites. According to actual situation, spare satellites may be deployed in orbit. The GEO satellites operate in orbit at an altitude of 35,786 kilometers and are located at 80°E, 110.5°E, and 140°E respectively. The IGSO satellites operate in orbit at an altitude of 35,786 kilometers and an inclination of the orbital planes of 55 degrees with reference to the equatorial plane. The MEO satellites operate in orbit at an altitude of 21,528 kilometers and an inclination of the orbital planes of 55 degrees with reference to the equatorial plane.

The BDS space constellation shall gradually take a transition from BDS-2’s to BDS-3’s and provides open services for users worldwide.

### 3.2 Coordinate System

The BeiDou Coordinate System is adopted by BDS, with the abbreviation as BDCS. The definition of BDCS is in accordance with the specifications of the International Earth Rotation and Reference System Service (IERS), and it is consistent with the definition of the China Geodetic Coordinate System 2000 (CGCS2000). BDCS and CGCS2000 have the same ellipsoid parameters. The definition of BDCS is as follows:

1. **Definition of origin, axis and scale**

   The origin is located at the Earth’s center of mass. The Z-Axis is the
direction of the IERS Reference Pole (IRP). The X-Axis is the intersection of the IERS Reference Meridian (IRM) and the plane passing through the origin and normal to the Z-Axis. The Y-Axis, together with Z-Axis and X-Axis, constitutes a right-handed orthogonal coordinate system.

The length unit is the international system of units (SI) meter.

(2) Definition of the BDCS Ellipsoid

The geometric center of the BDCS Ellipsoid coincides with the Earth’s center of mass, and the rotation axis of the BDCS Ellipsoid is the Z-Axis. The parameters of the BDCS Ellipsoid are shown in Table 3-1.

Table 3-1 Parameters of the BDCS Ellipsoid

<td>Ω_{e}=7.2921150×10^{-5} rad/s</td>
</tr>
</tbody>
</table>

3.3 Time System

The BeiDou navigation satellite system Time (BDT) is adopted by the BDS as time reference. BDT adopts the international system of units (SI) second as the base unit, and accumulates continuously without leap seconds. The start epoch of BDT is 00:00:00 on January 1, 2006 of Coordinated Universal Time (UTC). BDT connects with UTC via UTC (NTSC), and the deviation of BDT to UTC is maintained within 50 nanoseconds (modulo 1 second). The leap second information is broadcast in the navigation message.
4 Signal Specifications

4.1 Signal Structure

The B1I signal is composed of the carrier frequency, ranging code and navigation message. The ranging code and navigation message are modulated on carrier. The B1I signal is expressed as follows:

\[ S_{B1I}^j(t) = A_{B1I} C_{B1I}^j(t) D_{B1I}^j(t) \cos(2\pi f_1 t + \phi_{B1I}^j) \]

where,

Superscript \( j \): satellite number;

\( A_{B1I} \): amplitude of B1I;

\( C_{B1I}^j \): ranging code of B1I;

\( D_{B1I}^j \): data modulated on ranging code of B1I;

\( f_1 \): carrier frequency of B1I;

\( \phi_{B1I}^j \): carrier initial phase of B1I.

4.2 Signal Characteristics

4.2.1 Carrier Frequency

The signal carrier frequencies on board of the same satellite shall be coherently derived from a common reference frequency source. The nominal frequency of the B1I signal is 1561.098 MHz.

4.2.2 Modulation Mode

The B1I signal is modulated by Binary Phase Shift Keying (BPSK).

4.2.3 Polarization Mode

The B1I signal shall be Right-Hand Circularly Polarized (RHCP).
4.2.4 Carrier Phase Noise

The phase noise spectral density of the un-modulated carrier will allow a third-order phase locked loop with 10 Hz one-sided noise bandwidth to track the carrier to an accuracy of 0.1 radians (RMS).

4.2.5 Received Power Levels on Ground

The minimum received power levels on ground of the B1I signals are specified to be -163dBW. They are measured at the output of a 0 dBi RHCP user receiving antenna (or 3dBi linearly polarized user receiving antenna) when the satellites are above a 5-degree elevation angle.

4.2.6 Signal Multiplexing Mode

The signal multiplexing mode is Code Division Multiple Access (CDMA).

4.2.7 Signal Bandwidth

The bandwidth of the B1I signal is 4.092 MHz (centered at carrier frequency of the B1I signal).

4.2.8 Spurious

The transmitted spurious signal is shall not exceed -50dBc.

4.2.9 Signal Coherence

(1) The random jitters of the ranging code phase differentials (including satellite equipment group delay differential) between B1I, B2I and B3I shall be less than 1ns (1σ).

(2) For the B1I signal, the random jitter of the initial phase differential between the ranging code and the corresponding carrier shall be less than $3^{\circ}$ (1σ)
(relative to the carrier).

### 4.2.10 Equipment Group Delay Differential

The satellite equipment group delay is defined as the delay between the signal radiated output of a specific satellite (measured at the antenna phase center) and the output of that satellite’s on-board frequency source. The equipment group delay of B3I is regarded as the reference equipment group delay which is included in the clock correction parameter $a_0$ broadcasted in the navigation message. The uncertainty of this delay shall be less than 0.5ns (1σ).

The equipment group delay differential between the B1I signal and the B3I signal is given in $T_{GD1}$. The equipment group delay differential between the B2I signal and the B3I signal is given in $T_{GD2}$. $T_{GD1}$ and $T_{GD2}$ are broadcast in the navigation message, the uncertainties of which shall be less than 1ns (1σ).

### 4.3 Ranging Code Characteristics

The chip rate of the B1I ranging code (hereinafter referred to as $C_{B1I}$) is 2.046 Mcps, and the code length is 2046 chips.

The $C_{B1I}$ is generated by truncating a balanced Gold code with the last one chip. The balanced Gold code is generated by means of Modulo-2 addition of $G_1$ and $G_2$ sequences which are respectively derived from two 11-bit linear shift registers.

The generator polynomials for $G_1$ and $G_2$ are as follows:

\[
G_1(X) = 1 + X + X^7 + X^8 + X^9 + X^{10} + X^{11}
\]

\[
G_2(X) = 1 + X + X^2 + X^3 + X^4 + X^5 + X^8 + X^9 + X^{11}
\]

The initial phases of $G_1$ and $G_2$ are:

- $G_1$: 01010101010;
- $G_2$: 01010101010.

The generator of $C_{B1I}$ is shown in Figure 4-1.
Figure 4-1 The generator of $C_{B1I}$

The different phase shift of G2 sequence is accomplished by respective tapping in the shift register generating G2 sequence. By means of Modulo-2 addition of G2 with different phase shift and G1, a ranging code is generated for each satellite. The phase assignment of G2 sequence is shown in Table 4-1.

* Range code number sequences 1 through 37 have priority to be used by the satellites to ensure the backward compatibility with the existing receivers.
5 Navigation Message

5.1 General

5.1.1 Navigation Message Classification

Navigation messages are formatted in D1 and D2 based on their rate and structure. The rate of D1 navigation message which is modulated with 1 kbps secondary code is 50 bps. D1 navigation message contains basic navigation information (fundamental navigation information of the broadcasting satellites, almanac information for all satellites as well as the time offsets from other systems); while D2 navigation message contains basic navigation and wide area differential information (the BDS integrity, differential and ionospheric grid information) and its rate is 500 bps.

The D1 navigation message is broadcast by the B1I signals of MEO/IGSO satellites. The D2 navigation message is broadcast by the B1I signals of GEO satellites.

5.1.2 Navigation Message Information Type and Broadcasting

The broadcasting schemes of the basic navigation information and wide area differential information are shown in Table 5-1. The detailed structure, bit allocations, contents and algorithms will be described in later chapters.

</table>
5.1.3 Data Error Correction Coding Mode

The navigation message encoding involves both error control of BCH(15,11,1) and interleaving. The BCH code is 15 bits long with 11 information bits and error correction capability of 1 bit. The generator polynomial is \( g(X) = 1 + X + X^4 \).

The navigation message bits are grouped every 11 bits in sequence first. The serial/parallel conversion is made and the BCH(15,11,1) error correction encoding is performed in parallel. Parallel/serial conversion is then carried out for every two parallel blocks of BCH codes by turns of 1 bit to form an interleaved code of 30 bits length. The implementation is shown in Figure 5-1.

![Figure 5-1 Error correction encoding and interleaving of down-link navigation message](image)

The implementation of BCH (15,11,1) encoder is shown in Figure 5-2. Initially the four stages of the shift register are all reset to zero, Gate1 is on and Gate2 is off. The 11 bits of information block \( X \) are sent into a dividing circuit \( g(X) \). Meantime the information bits are sent out of the encoder through gate “or” as the output. The dividing operation finishes when all the 11 bits have been sent in and then the states of the four register stages represent the parity check bits. Now switch Gate 1 off and Gate 2 on. The four parity check bits are shifted out of the encoder through gate “or” to form a 15 bits code in combination with the output 11 bits of information block. Then switch Gate1 on and Gate2 off and send in the next information block and the procedure above is repeated again.
For the received navigation message by receivers near ground a serial/parallel conversion by turns of 1 bit is required first, followed by an error correction decoding of BCH(15,11,1) in parallel. Then a parallel/serial conversion is carried out for each 11 bits block to form a 22 bits information code in sequence. The processing is shown in Figure 5-3.

The decoding logic of BCH(15,11,1) is shown in Figure 5-4. The initial states of the four register stages are all zeros. BCH codes are sent in bit by bit into a division circuit and a fifteen stages buffer simultaneously. When all fifteen bits of a BCH code are inputted, the ROM list circuit forms a fifteen-bit table based on the states D3, D2, D1 and D0 of the four register stages. Then the 15 bits in the table and 15 bits in the buffer are Modulo-2 added and an error corrected information code obtained is output. The ROM table list is shown in Table 5-2.

The interleaving pattern of 30 bits code is as follows:

\[ X_1^1 \quad X_2^1 \quad X_1^2 \quad X_2^2 \quad \ldots \quad X_1^{11} \quad X_2^{11} \quad P_1^1 \quad P_2^1 \quad P_1^2 \quad P_2^2 \quad P_1^3 \quad P_2^3 \quad P_1^4 \quad P_2^4 \]
where, $X^i_j$ is the information bit, subscript i stands for the bit in BCH code of block i and i=1 or 2; superscript j stands for the information bit j in block i and j=1 to 11; $P^i_m$ is the check parity bit, subscript i stands for the bit in BCH code of block i and i=1 or 2; superscript m stands for the parity bit m in BCH code of block i and m=1 to 4.

5.2 D1 Navigation Message

5.2.1 Secondary Code Modulated on D1 navigation message

For D1 navigation message of rate 50 bps, a secondary code of Neumann-Hoffman (NH) code is modulated on ranging code. The period of NH code is selected as long as the duration of a navigation message bit. The bit duration of NH code is the same as one period of the ranging code. Shown as in Figure 5-5, the duration of one navigation message bit is 20 milliseconds and the ranging code period is 1 millisecond. Thus the NH code (00000100110101001110) with length of 20 bits, rate 1 kbps and bit duration of 1 millisecond is adopted. It is modulo-2 added to the ranging code synchronously with navigation message bit.
5.2.2 D1 Navigation Message Frame Structure

The navigation message in format D1 is structured in the superframe, frame and subframe. Every superframe has 36000 bits and lasts 12 minutes. Every superframe is composed of 24 frames (24 pages). Every frame has 1500 bits and lasts 30 seconds. Every frame is composed of 5 subframes. Every subframe has 300 bits and lasts 6 seconds. Every subframe is composed of 10 words. Every word has 30 bits and lasts 0.6 second.

Every word consists of navigation message data and parity bits. In the first word of every subframe, the first 15 bits is not encoded and the following 11 bits are encoded in BCH(15,11,1) for error correction. So there is only one group of BCH code contained and there are altogether 26 information bits in the word. For all the other 9 words in the subframe both BCH(15,11,1) encoding for error control and interleaving are involved. Each of the 9 words of 30 bits contains two blocks of BCH codes and there are altogether 22 information bits in it. (reference paragraph 5.1.3)

The frame structure in format D1 is shown in Figure 5-6.

![Figure 5-6 Frame structure of navigation message in format D1](image-url)
5.2.3 D1 Navigation Message Detailed Structure

The main information contents of navigation message in format D1 are basic navigation information, including fundamental navigation information of the broadcasting satellites (seconds of week, week number, user range accuracy index, autonomous satellite health flag, ionospheric delay model parameters, satellite ephemeris parameters and their age, satellite clock correction parameters and their age and equipment group delay differential), almanac and BDT offsets from other systems (UTC and other navigation satellite systems).

The D1 frame structure and information contents are shown in Figure 5-7. The fundamental navigation information of the broadcasting satellite is in subframes 1, 2 and 3. The subframes 4 and 5 are divided into 24 pages and shall be used to broadcast almanac and time offsets from other systems for all the satellites.

![Diagram of D1 Navigation Message Structure](image)

**Figure 5-7 Information contents of navigation message in format D1**

The bit allocations of format D1 are shown in Figure 5-8~5-11. Thereinto, pages 11~24 of subframe 5 are used to broadcast the expanded almanac information which contain the almanac parameters and the satellite health information for SV ID 31 through 63.

(Not: When AmEpID is equal to “11”, page 24 of subframe 5 is used to broadcast the satellite health information. Otherwise, page 24 of subframe 5 is defined as a reserved page, i.e., bits 51 through 300 of this page are reserved.)
5.2.4 D1 Navigation Message Content and Algorithm

5.2.4.1 Preamble (Pre)

Bits 1 through 11 of each subframe are preamble (Pre) of “11100010010” from modified Barker code of 11 bits. SOW count occurs at the leading edge of the preamble first bit which is for time scale synchronization.

5.2.4.2 Subframe identification (FraID)

Bits 16, 17 and 18 of every subframe are for subframe identification (FraID). The detailed definitions are as follows:

<table>
<thead>
<tr>
<th>Code</th>
<th>001</th>
<th>010</th>
<th>011</th>
<th>100</th>
<th>101</th>
<th>110</th>

</tr>
</tbody>
</table>

5.2.4.3 Seconds of Week (SOW)

Bits 19~26 and bits 31~42, altogether 20 bits of the each subframe are for seconds of week (SOW) which is defined as the number of seconds that have occurred since the last Sunday, 00:00:00 of BDT. The SOW count occurs at the leading edge of preamble first bit of the subframe.

5.2.4.4 Week Number (WN)

There are altogether 13 bits for week number (WN) which is the integral week count of BDT with the range of 0 through 8191. Week number count started from zero at 00:00:00 on Jan. 1, 2006 of BDT.

5.2.4.5 User Range Accuracy Index (URAI)
The user range accuracy (URA) is used to describe the signal-in-space accuracy in meters. There are 4 bits for the user range accuracy index (URAI). The range of URAI is from 0 to 15. See Table 5-4 for the corresponding relationship between URAI and URA.

Table 5-4 Corresponding relationship between URAI and URA

</tr>
<tr>
<td>1111</td>
<td>15</td>
<td>URA &gt; 6144.00</td>
</tr>
</tbody>
</table>

When an URAI is received by the user, the corresponding URA (X) is computed by the following equations:

If $0 \leq N < 6$, $X = 2^{N/2+1}$;

If $6 \leq N < 15$, $X = 2^{N-2}$;

If $N=15$, it means the satellite is in maneuver or there is no accuracy prediction;
If \( N=1,3 \) and 5, \( X \) should be rounded to 2.8, 5.7, and 11.3 meters, respectively.

### 5.2.4.6 Autonomous Satellite Health flag (SatH1)

The autonomous satellite health flag (SatH1) occupies 1 bit. “0” means broadcasting satellite is good and “1” means not.

### 5.2.4.7 Ionospheric Delay Model Parameters (\( \alpha_n, \beta_n \))

There are 8 parameters, altogether 64 bits for ionospheric delay model. All the 8 parameters are in two’s complement. See Table 5-5 for details.

<table>
<thead>
<tr>
<th>Parameter</th>

</tr>
</tbody>
</table>

* Parameters so indicated are two’s complement, with the sign bit (+ or –) occupying the MSB.

The user computers the vertical ionospheric delay correction \( I_z(t) \) with the 8 parameters and Klobuchar model as follows:

\[
I_z(t) = \begin{cases} 
5 \times 10^{-9} + A_2 \cos \left( \frac{2\pi(t - 50400)}{A_4} \right), |t - 50400| < A_4/4 \\
5 \times 10^{-9}, |t - 50400| \geq A_4/4 
\end{cases}
\]
where, $I_z(t)$ is the vertical ionospheric delay in seconds for B1I, t is the local time (range 0~86400 sec) for the place under the intersection point (M) of ionosphere and the direction from receiver to satellite. It is computed as:

$$t = (t_e + \lambda_M \times 43200/\pi) \mod 86400$$

where, $t_e$ is the SOW in BDT computed by user. $\lambda_M$ is geodetic longitude of the Earth projection of the ionospheric intersection point in radians.

$A_2$ is the amplitude of Klobuchar cosine curve in the day time computed from the $\alpha_n$.

$$A_2 = \sum_{n=0}^{3} \alpha_n \left| \frac{\phi_M}{\pi} \right|^n, \quad A_2 \geq 0$$

$$0, \quad A_2 < 0$$

$A_4$ is the period of cosine curve in seconds. It is computed from the $\beta_n$.

$$A_4 = \sum_{n=0}^{3} \beta_n \left| \frac{\phi_M}{\pi} \right|^n$$

$$172800, \quad A_4 \geq 172800$$

$$172800 > A_4 \geq 72000$$

$$72000, \quad A_4 < 72000$$

where, $\phi_M$ is the geographic latitude of earth projection of the ionosphere intersection point. The geographic latitude $\phi_M$ and longitude $\lambda_M$ of the intersection point M are computed as:

$$\phi_M = \arcsin \left( \sin \phi_u \cdot \cos \psi + \cos \phi_u \cdot \sin \psi \cdot \cos A \right)$$

$$\lambda_M = \lambda_u + \arcsin \left( \frac{\sin \psi \cdot \sin A}{\cos \phi_M} \right)$$

where, $\phi_M$ and $\lambda_M$ are in radians.$\phi_u$ is the user’s geographic latitude in radians. A is the satellite azimuth from the user location in radians. $\psi$ is the Earth’s central angle in radians between the user location and ionospheric intersection point. It is computed as: 
\[ \psi = \frac{\pi}{2} - E - \arcsin\left(\frac{R}{R + h} \cdot \cos E\right) \]

where, \( R \) is the mean radius of the Earth (6378 km). \( E \) is the satellite elevation from the user’s location in radians. \( h \) is the height of ionosphere (375 km).

\( I_{B1I}(t) \) is defined as the ionospheric delay along the B1I propagation path (in seconds), which can be obtained from \( I'(t) \) through the equation as follows:

\[ I_{B1I}(t) = \frac{1}{\sqrt{1 - \left(\frac{R}{R + h} \cdot \cos E\right)^2}} \cdot I'(t) \]

The dual-frequency (B1I and B3I) user shall correct the ionospheric delay by applying the expression as follows:

\[ PR = \frac{PR_{B3I} - k_{1,3}(f) \cdot PR_{B1I}}{1 - k_{1,3}(f)} + C \cdot k_{1,3}(f) \cdot T_{GD1} \]

where,

\( PR \): pseudorange corrected for ionospheric effects;

\( PR_{B1I} \): pseudorange measured on B1I (corrected by the satellite clock correction but not corrected by \( T_{GD1} \));

\( PR_{B3I} \): pseudorange measured on B3I;

\( T_{GD1} \): equipment group delay differential on B1I;

\( C \): the light speed, and its value is 2.99792458 \times 10^8 \) m/s.

### 5.2.4.8 Age of Data, Clock (AODC)

Age of data, clock (AODC) is updated at the start of each hour in BDT, and it is 5 bits long with definitions as follows:
Table 5-6 AODC definitions

<table>
<thead>
<tr>
<th>AODC</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 25</td>
<td>Age of the satellite clock correction parameters in hours</td>

<tr>
<td>31</td>
<td>Age of the satellite clock correction parameters is over seven days</td>
</tr>
</tbody>
</table>

5.2.4.9 Clock Correction Parameters \((t_{oc}, a_0, a_1, a_2)\)

Clock correction parameters are \(t_{oc}, a_0, a_1, a_2\) in 74 bits altogether. \(t_{oc}\) is the reference time of clock parameters in seconds with the effective range of 0~604792. Other 3 parameters are two’s complement.

The value of \(t_{oc}\) shall monotonically increase over the week and shall change if any of the clock parameters change. Normally, clock correction parameters are updated every one hour and at the start of BDT hours. The value of \(t_{oc}\) are integral points.

New navigation message will be uploaded when abnormality occurs, the clock correction parameters may be updated at non-integral points. At this time, \(t_{oc}\) will change and no longer be integral points.

When the value of \(t_{oc}\) has not been integral points (i.e., there has been an update at a non-integral point recently), if the clock correction parameters being updated at non-integral points again, \(t_{oc}\) will change
correspondingly to ensure it is different from the previous value.

Whether it is normal or not, clock correction parameters are always updated at the start of a superframe.

The definitions of clock correction parameters are listed in Table 5-7.

Table 5-7 Clock correction parameters

* Parameters so indicated are two’s complement, with the sign bit (+ or –) occupying the MSB.

The system time computation is as follows:

The user is able to compute BDT at time of signal transmission as:

\[ t = t_{sv} - \Delta t_{sv} \]

where, \( t \) is BDT in seconds at time of signal transmission; \( t_{sv} \) is the effective satellite ranging code phase time in seconds at time of signal transmission; \( \Delta t_{sv} \) is the offset of satellite ranging code phase time in seconds and is given by the equation:

\[ \Delta t_{sv} = a_0 + a_1(t - t_{oc}) + a_2(t - t_{oc})^2 + \Delta t_r \]

where, \( t \) can be replaced by \( t_{sv} \) regardless of its sensitivity.

\( \Delta t_r \) is the correction term to relativistic effect with value of

\[ \Delta t_r = F \cdot e \cdot \sqrt{A} \cdot \sin E_k \]

\( e \) is the orbit eccentricity, which is given in ephemeris of the broadcasting satellite;

\( \sqrt{A} \) is the square root of semi-major axis of satellite orbit, which is
given in ephemeris of the broadcasting satellite;

\[ E_k \] is eccentric anomaly of satellite orbit, which is given in ephemeris of the broadcasting satellite;

\[ F = -2\mu^{1/2}/C^2; \]
\[ \mu = 3.986004418 \times 10^{14} \, \text{m}^3/\text{s}^2, \] is the value of geocentric gravitational constant;

\[ C = 2.99792458 \times 10^8 \, \text{m/s}, \] is the light speed.

### 5.2.4.10 Equipment Group Delay Differential (T\(_{GD1}\),T\(_{GD2}\))

The equipment group delay differential (T\(_{GD1}\),T\(_{GD2}\)) in the satellite is 10 bits long respectively. It is in two’s complement with sign bit (+ or –) occupying MSB. Sign bit “0” means positive and “1” means negative. The scale factor is 0.1 and the unit is nanoseconds.

The single-frequency B1I user should make a further correction as follows:

\[ (\Delta t_{sv})_{B1I} = \Delta t_{sv} - T_{GD1} \]

The single-frequency B2I user should make a further correction as follows:

\[ (\Delta t_{sv})_{B2I} = \Delta t_{sv} - T_{GD2} \]

where, \( \Delta t_{sv} \) is the offset of satellite ranging code phase time in seconds and the detailed algorithm is defined in paragraph 5.2.4.9.

### 5.2.4.11 Age of Data, Ephemeris (AODE)

Age of data, ephemeris (AODE) is updated at the start of each hour in BDT, and it is 5 bits long with definitions as follows:
### Table 5-8 AODE definitions

<table>

#### 5.2.4.12 Ephemeris Parameters \((t_{oe}, \sqrt{A}, e, \omega, \Delta n, M_0, \Omega_0, \dot{\Omega}, i_0, \text{IDOT}, C_{uc}, C_{us}, C_{re}, C_{rs}, C_{ic}, C_{is})\)

The ephemeris parameters describe the satellite orbit during the curve fit interval, including 15 orbit parameters and an ephemeris reference time.

The value of \(t_{oe}\) shall monotonically increase over the week and shall change if any of the ephemeris parameters change. If \(t_{oe}\) changes then \(t_{oe}\) shall also change. Normally, ephemeris parameters are updated every hour and at the start of every BDT hour. The value of \(t_{oe}\) are integral points.

New navigation message will be uploaded when abnormality occurs, the ephemeris parameters may be updated at non-integral points. At this time, \(t_{oe}\) will change and no longer be integral points. When the value of \(t_{oe}\) has not been integral points (i.e., there has been an update at a
non-integral point recently), if the ephemeris parameters being updated at non-integral points again, \( t_{oe} \) will change correspondingly to ensure it is different from the previous value.

Whether it is normal or not, ephemeris parameters are always updated at the start of a superframe.

The definitions of ephemeris parameters are listed in Table 5-9.

### 5.2.4.13 Page number (Pnum)

Bits 44 through 50, 7 bits altogether of subframe 4 and subframe 5 are the page numbers (Pnum). Both subframe 4 and subframe 5 have 24 pages (i.e., pages 1 through 24) which are identified through the page number (Pnum).

The almanac parameters of SV ID 1 through 24 are arranged in pages 1 through 24 of subframe 4. The almanac parameters of SV ID 25 through 30 are arranged in pages 1 through 6 of subframe 5. The page
number corresponds to the SV ID one by one. Furthermore, the almanac parameters of SV ID 31 through 43, 44 through 56, and 57 through 63 can be arranged in pages 11 through 23 of subframe 5 by using the time-sharing broadcasting scheme.

5.2.4.14 Identification of Expanded Almanacs (AmEpID)

AmEpID is the identification of the expanded almanac information, which has a length of 2 bits. AmEpID is provided to enable the user to detect whether pages 11 through 24 of subframe 5 are used to broadcast the expanded almanac information (i.e., the almanac parameters and the satellite health information of SV ID 31 through 63).

When AmEpID is equal to “11”, pages 11 through 23 of subframe 5 can be used to broadcast the almanac parameters for SV ID 31 through 63, and page 24 of subframe 5 is used to broadcast the satellite health information for SV ID 31 through 63. Otherwise, pages 11 through 24 of subframe 5 are reserved.

5.2.4.15 Almanac Parameters （t_{oa}, \sqrt{A}, e, \omega, M_0, \Omega_0, \dot{\Omega}, \delta, a_0, a_1, AmID）

Almanac parameters are updated within every 7 days.

Definitions, characteristics, and user algorithms of almanac parameters are listed in Tables 5-12, 5-13, 5-14 and 5-15 respectively.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>

</tr>
<tr>
<td>\omega</td>
<td>Argument of Perigee</td>
</tr>
</tbody>
</table>
AmID has a length of 2 bits, and its value is effective when AmEpID is equal to “11”. AmID can be used to identify the expanded almanac information (i.e., the almanac parameters and the satellite health information of SV ID 31 through 63) which are time-sharing broadcasted in pages 11 through 24 of subframe 5.

The user shall use AmEpID first to determine whether pages 11 through 23 of subframe 5 are used to broadcast the almanac parameters. When AmEpID is equal to “11”, the user shall further use AmID to identify the almanac parameters of SV ID 31 through 63 in pages 11 through 23 of subframe 5; otherwise, the value of AmID is invalid and the user shall not use pages 11 through 23 of subframe 5. The broadcasting scheme for the almanac parameters of SV ID 31 through 63 is defined in Table 5-13.

Z_k &= y_k \sin i
\end{align*}
\]

Computed GEO/MEO/IGSO satellite coordinates in BDCS

* In the equations, “t” is the time of signal transmission in BDT. “t_k” is the total time offset between time t and Almanac reference time t_{oa} taking account of beginning or end of a week crossover. That is, subtract 604800 seconds from t_k if t_k is greater than 302400, add 604800 seconds to t_k if t_k is less than -302400.

** For MEO/IGSO satellites, i_0=0.30 semi-circles; for GEO satellites, i_0=0.00.

Almanac time computation is as follows:

\[
t = t_{sv} - \Delta t_{sv}
\]

where, t is BDT in seconds at time of signal transmission; t_{sv} is the effective satellite ranging code phase time in seconds at time of signal transmission; \(\Delta t_{sv}\) is the offset of satellite ranging code phase time in seconds and is given by the equation:

\[
\Delta t_{sv} = a_0 + a_1(t - t_{oa})
\]

where, t can be replaced by t_{sv} regardless of its sensitivity. The almanac reference time t_{oa} is counted from the starting time of almanac week number (WN_a).

**5.2.4.16 Almanac Week Number (WN_a)**

Almanac week number (WN_a) of 8 bits is the BDT integer week count (Modulo 256) with effective range of 0 to 255.
5.2.4.17 Satellite Health Information (Heaᵢ, i=1~43)

The satellite health information (Heaᵢ) occupies 9 bits. The 9th bit indicates the satellite clock health flag, while the 8th bit indicates the B1I signal health status, the 7th bit indicates the B2I signal health status, the 6th bit indicates the B3I signal health status and the 2nd bit indicates the information health status. The definitions are in Table 5-16.

<table>

</tbody>
</table>

* The satellite clock is unavailable if the other 8 bits are all “0”; the satellite is in failure or permanently shut off if the last 8bits are all “1”; the definition is reserved if the other 8 bits are in other values.
** The signal power is 10 dB lower than nominal value.

Heaᵢ (i=1~30) correspond to the satellite health information of SV ID 1 through 30. By using time-sharing broadcasting scheme, Heaᵢ (i=31~43) correspond to the satellite health information of SV ID 31 through 43, 44 through 56, and 57 through 63.
The user shall use AmEpID first to determine whether page 24 of subframe 5 is used to broadcast the satellite health information. When AmEpID is equal to “11”, the user shall further use AmID to identify the satellite health information of SV ID 31 through 63 in page 24 of subframe 5; otherwise, the value of AmID is invalid and the user shall not use page 24 of subframe 5. The broadcasting scheme for the satellite health information of SV ID 31 through 63 is defined in Table 5-17.

5.2.4.18 Time Parameters relative to UTC (A₀UTC, A₁UTC, Δt₇LS, WN₇LSF, DN, Δt₇LSF)

These parameters indicate the relationship between BDT and UTC. Definitions of the parameters are listed in Table 5-18.

Table 5-18 Parameters relative to UTC

<table>
<thead>
<tr>
<th>Parameter</th>
<th>No. of bits</th>
<th>Scale factor(LSB)</th>
<th>Effective range</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>A₀UTC</td>

<tr>
<td>WN₇LSF</td>
<td>8</td>
<td>1</td>
<td>—</td>
<td>week</td>
</tr>
<tr>
<td>DN</td>
<td>8</td>
<td>1</td>
<td>6</td>
<td>day</td>
</tr>
<tr>
<td>Δt₇LSF</td>
<td>8*</td>
<td>1</td>
<td>—</td>
<td>s</td>
</tr>
</tbody>
</table>

* Parameters so indicated are two’s complement, with the sign bit (+ or −) occupying the MSB.

A₀UTC: BDT clock bias relative to UTC;
A₁UTC: BDT clock rate relative to UTC;
Δt_{LS}: Delta time due to leap seconds before the new leap second effective;

WN_{LSF}: Week number of the new leap second, and its value consist of eight bits which shall be a modulo 256 binary representation of the week number to which the DN is referenced. The absolute value of the difference between the untruncated WN and WN_{LSF} values shall not exceed 127.

DN: Day number of week of the new leap second;

Δt_{LSF}: Delta time due to leap seconds after the new leap second effective;

Conversion from BDT into UTC:

The broadcast UTC parameters, the WN_{LSF} and DN values make users compute UTC with error not greater than 1 microsecond.

Depending upon the relationship of the effectivity time of leap second event and user’s current BDT, the following three different cases of UTC/BDT conversion exist.

1) Whenever the effectivity time indicated by the WN_{LSF} and the DN values is not in the past (relative to the user’s present time), and the user’s current time t_E is prior to DN+2/3, the UTC/BDT relationship is given by:

\[ t_{UTC} = (t_E - \Delta t_{UTC}) \mod 86400, \text{ seconds} \]

\[ \Delta t_{UTC} = \Delta t_{LS} + A_{0UTC} + A_{1UTC} \times t_E, \text{ seconds} \]

where, t_E is the SOW in BDT computed by user.

2) Whenever the user’s current time t_E falls within the time span of DN+2/3 to DN+5/4, proper accommodation of leap second event with possible week number transition is provided by the following equation for UTC:

\[ t_{UTC} = W \mod (86400 + \Delta t_{LSF} - \Delta t_{LS}), \text{ seconds} \]

where,
\[
W = (t_E - \Delta t_{UTC} - 43200) \text{[modulo 86400]} + 43200, \text{ seconds}
\]
\[
\Delta t_{UTC} = \Delta t_{LS} + A_{0OUT} + A_{1UTC} \times t_E, \text{ seconds}
\]

3) Whenever the effectivity time of leap second event, as indicated by the WN_{LSF} and DN values, is in the past (relative to the user’s current time), and the user’s current time \( t_E \) is after DN+5/4, the UTC/BDT relationship is given by:

\[
t_{UTC} = (t_E - \Delta t_{UTC}) \text{[modulo86400]}, \text{ seconds}
\]

where,

\[
\Delta t_{UTC} = \Delta t_{LSF} + A_{0UTC} + A_{1UTC} \times t_E, \text{ seconds}
\]

The parameter definitions are the same with those in case 1).

5.2.4.19 Time Parameters relative to GPS time \( (A_{0GPS}, A_{1GPS}) \)

These parameters indicate the relationship between BDT and GPS time as in Table 5-19. (Not broadcast temporarily)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>No. of Bits</th>
<th>Scale factor (LSB)</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>( A_{0GPS} )</td>
<td>14*</td>
<td>0.1</td>
<td>ns</td>
</tr>
<tr>
<td>( A_{1GPS} )</td>
<td>16*</td>
<td>0.1</td>
<td>ns/s</td>
</tr>
</tbody>
</table>

* Parameters so indicated are two’s complement, with the sign bit (+ or –) occupying the MSB.

\( A_{0GPS} \): BDT clock bias relative to GPS time;

\( A_{1GPS} \): BDT clock rate relative to GPS time.

The relationship between BDT and GPS time is as follows:

\[
t_{GPS} = t_E - \Delta t_{GPS}
\]

where, \( \Delta t_{GPS} = A_{0GPS} + A_{1GPS} \times t_E; t_E \) is the SOW in BDT computed by user.

5.2.4.20 Time Parameters relative to Galileo time \( (A_{0Gal}, A_{1Gal}) \)

These parameters indicate the relationship between BDT and Galileo time as in Table 5-20. (Not broadcast temporarily)
### Table 5-20 Time parameters relative to Galileo time

<table>
<thead>
<tr>
<th>Parameter</th>
<th>No. of Bits</th>
<th>Scale factor (LSB)</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>$A_{0\text{Gal}}$</td>
<td>14$^*$</td>
<td>0.1</td>
<td>ns</td>
</tr>
<tr>
<td>$A_{1\text{Gal}}$</td>
<td>16$^*$</td>
<td>0.1</td>
<td>ns/s</td>
</tr>
</tbody>
</table>

* Parameters so indicated are two’s complement, with the sign bit (+ or –) occupying the MSB.

$A_{0\text{Gal}}$: BDT clock bias relative to Galileo system time;

$A_{1\text{Gal}}$: BDT clock rate relative to Galileo system time.

Relationship between BDT and Galileo system time is as follows:

$$t_{\text{Gal}} = t_{E} - \Delta t_{\text{Gal}}$$

where, $\Delta t_{\text{Gal}} = A_{0\text{Gal}} + A_{1\text{Gal}} \times t_{E}$; $t_{E}$ is the SOW in BDT computed by user.

#### 5.2.4.21 Time Parameters relative to GLONASS time ($A_{0\text{GLO}}, A_{1\text{GLO}}$)

These parameters indicate the relationship between BDT and GLONASS time as in Table 5-21. (Not broadcast temporarily)

### Table 5-21 Time parameters relative to GLONASS time

<table>
<thead>
<tr>
<th>Parameter</th>
<th>No. of Bits</th>
<th>Scale factor (LSB)</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>$A_{0\text{GLO}}$</td>
<td>14$^*$</td>
<td>0.1</td>
<td>ns</td>
</tr>
<tr>
<td>$A_{1\text{GLO}}$</td>
<td>16$^*$</td>
<td>0.1</td>
<td>ns/s</td>
</tr>
</tbody>
</table>

* Parameters so indicated are two’s complement, with the sign bit (+ or –) occupying the MSB.

$A_{0\text{GLO}}$: BDT clock bias relative to GLONASS time;

$A_{1\text{GLO}}$: BDT clock rate relative to GLONASS time.

Relationship between BDT and GLONASS time is as follows:

$$t_{\text{GLO}} = t_{E} - \Delta t_{\text{GLO}}$$

where, $\Delta t_{\text{GLO}} = A_{0\text{GLO}} + A_{1\text{GLO}} \times t_{E}$; $t_{E}$ is the SOW in BDT computed by user.
5.3 D2 Navigation Message

5.3.1 D2 Navigation Message Frame Structure

The navigation message in format D2 is structured with superframe, frame and subframe. Every superframe is 180000 bits long, lasting 6 minutes. Every superframe is composed of 120 frames each with 1500 bits and lasting 3 seconds. Every frame is composed of 5 subframes, each with 300 bits and lasting 0.6 second. Every subframe is composed of 10 words, each with 30 bits and lasting 0.06 second.

Every word is composed of navigation message data and parity bits. The first 15 bits in word 1 of every subframe is not encoded, and the last 11 bits is encoded in BCH(15,11,1) for error correction. For the other 9 words of the subframe both BCH(15,11,1) encoding and interleaving are involved. Thus there are 22 information bits and 8 parity bits in each word. See Figure 5-12 for the detailed structure.

![Diagram of D2 navigation message structure](image)

Figure 5-12 Structure of navigation message in format D2

5.3.2 D2 Navigation Message Detailed structure

Information in format D2 includes: the basic navigation information
of the broadcasting satellite, almanac, time offset from other systems, integrity and differential correction information of BDS and ionospheric grid information as shown in Figure 5-13. The subframe 1 shall be subcommutated 10 times via 10 pages. The subframe 2, subframe 3 and subframe 4 shall be subcommutated 6 times each via 6 pages. The subframe 5 shall be subcommutated 120 times via 120 pages.

**Figure 5-13 Information contents of navigation message in format D2**

The bit allocation for each subframe in format D2 is shown in Figures 5-14 through 5-18. Thereinfo, pages 1 through 6 of subframe 4 are used to broadcast the expanded BDS integrity and differential correction information, pages 103 through 116 of subframe 5 are used to broadcast the expanded almanac information, and the 150 LSBs of pages 1 through 10 in subframe 1, pages 14 through 34, pages 74 through 94 and pages 117 through 120 of subframe 5 are reserved.

(Note: When AmEpID is equal to “11”, pages 103 through 115 of subframe 5 are used to broadcast the almanac parameters. Otherwise, pages 103 through 115 of subframe 5 are defined as reserved pages, i.e., bits 51 through 300 of these pages are reserved.)
### Figure 5-18-33 Bit allocation for page 116 of subframe 5 in format D2

(Note: When AmEpID is equal to “11”, page 116 of subframe 5 is used to broadcast the satellite health information. Otherwise, page 116 of subframe 5 is defined as a reserved page, i.e., bits 51 through 300 of this page are reserved.)

### Figure 5-18-34 Bit allocation for reserved pages 14 through 34, 74 through 94, and 117 through 120 of subframe 5 in format D2
5.3.3 D2 Navigation Message Content and Algorithm

D2 navigation message contains basic navigation information and wide area differential information.

5.3.3.1 Basic Navigation Information

D2 navigation message contains all the basic navigation information as follows:

Fundamental navigation information of the broadcasting satellite:
- Preamble (Pre)
- Subframe identification (FraID)
- Seconds of week (SOW)
- Week number (WN)
- User range accuracy index (URAI)
- Autonomous satellite health flag (SatHl)
- Ionospheric delay model parameters ($\alpha_n, \beta_n, n=0~3$)
- Equipment group delay differential ($T_{GD1}, T_{GD2}$)
- Age of data, clock (AODC)
- Clock correction parameters ($t_{oc}, a_0, a_1, a_2$)
- Age of data, ephemeris (AODE)
- Ephemeris parameters ($t_{oc}, \sqrt{\lambda}, e, \omega, \Delta n, M_0, \Omega_0, \dot{\Omega}, i_0, IDOT, C_{uc}, C_{us}, C_{rc}, C_{rs}, C_{ic}, C_{is}$)

Page number (Pnum)

Almanac information:
- Identification of expanded almanacs (AmEpID)
- Almanac parameters ($t_{oa}, \sqrt{\lambda}, e, \omega, M_0, \Omega_0, \dot{\Omega}, \delta_i, a_0, a_1, AmID$)
- Almanac week number (WN$_i$)
- Satellite health information (Heai, i=1~43)
Time offsets from other systems:

- Time parameters relative to UTC \((A_{0UTC}, A_{1UTC}, \Delta t_{LS}, WN_{LSF}, DN, \Delta t_{LSF})\)
- Time parameters relative to GPS time \((A_{0GPS}, A_{1GPS})\)
- Time parameters relative to Galileo time \((A_{0Gal}, A_{1Gal})\)
- Time parameters relative to GLONASS time \((A_{0GLO}, A_{1GLO})\)

The definition of basic navigation information is the same as that in format D1, except the page number (Pnum), seconds of week (SOW), identification of expanded almanacs (AmEpID), and identification of time-sharing broadcasting (AmID) which are different from those in format D1. Thus only the meanings of Pnum, SOW, AmEpID, and AmID are given as follows.

1. **Page number (Pnum)**
   
   In format D2, the information of subframe 5 is broadcast via 120 pages and the page number is identified by Pnum.

2. **Seconds of week (SOW)**
   
   In format D2, bits 19 through 26 and bits 31 through 42, altogether 20 bits of every subframe are for the seconds of week (SOW). SOW count starts from zero at 00:00:00 of BDT on every Sunday.
   
   In format D2, SOW refers to the leading edge of preamble first bit in subframe 1 of each frame.

3. **Identification of expanded almanacs (AmEpID)**
   
   In format D2, AmEpID is the identification of the expanded almanac information, which has a length of 2 bits. AmEpID is provided to detect whether pages 103 through 116 of subframe 5 are used to broadcast the expanded almanac information (i.e., the almanac parameters and the satellite health information of SV ID 31 through 63).
   
   When AmEpID is equal to “11”, pages 103 through 115 of subframe 5 can be used to broadcast the almanac parameters for SV ID 31 through 63, and page
116 of subframe 5 is used to broadcast the satellite health information for SV ID 31 through 63. Otherwise, pages 103 through 116 of subframe 5 are reserved.

(4) Identification of time-sharing broadcasting (AmID)

In format D2, AmID has a length of 2 bits, and its value is effective when AmEpID is equal to “11”. AmID can be used to identify the expanded almanac information (i.e., the almanac parameters and the satellite health information of SV ID 31 through 63) which are time-sharing broadcasted in pages 103 through 116 of subframe 5.

The user shall use AmEpID first to determine whether pages 103 through 116 of subframe 5 are used to broadcast the expanded almanac information. When AmEpID is equal to “11”, the user shall further use AmID to identify the expanded almanac information of SV ID 31 through 63 in pages 103 through 116 of subframe 5; otherwise, the value of AmID is invalid and the user shall not use pages 103 through 116 of subframe 5.

For format D2, The broadcasting scheme for the almanac parameters of SV ID 31 through 63 is defined in Table 5-22. The broadcasting scheme for the satellite health information is the same as the scheme for the satellite health information in D1 navigation message, which can refer to Table 5-17.

Table 5-22 Broadcasting scheme for the almanac parameters of SV ID 31~63

"China Satellite Navigation Office 2019"
5.3.3.2 Page Number for Basic Navigation Information (Pnum1)

Bits 43 through 46, altogether 4 bits of subframe 1 are for page number of the basic navigation information (Pnum1). Pnum1 is broadcast in pages 1 through 10 of subframe 1.

5.3.3.3 Page Number for Integrity and Differential Correction Information (Pnum2)

Bits 44 through 47, altogether 4 bits of the subframe 2 are for the page number of the integrity and differential correction information (Pnum2). Pnum2 are broadcast in pages 1 through 6 of subframe 2.

5.3.3.4 Satellite Health Flag for Integrity and Differential Correction Information (SatH2)

The satellite health flag for integrity and differential correction information SatH2 is in 2 bits. The MSB indicates the check result of the satellite for the received up-link regional user range accuracy (RURA), user differential range error (UDRE) and equivalent clock correction (Δt). The LSB indicates the check result of the satellite for received up-link ionospheric grid information.

See Table 5-23 for detailed definitions.

<td>Ionospheric grid information is good by check</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>Ionospheric grid information is bad by check</td>
</tr>
</tbody>
</table>
5.3.3.5 Identification of Expanded BDS Integrity and differential correction information (BDEpID)

BDEpID, which has a length of 2 bits, is provided to identify whether pages 1 through 6 of subframe 4 are used to broadcast the expanded BDS integrity and differential correction information.

When BDEpID is equal to “11”, pages 1 through 6 of subframe 4 can be used to broadcast the BDS satellite identification of integrity and differential correction information (BDID_i, i=31~63), regional user range accuracy (RURA), equivalent clock correction (Δt), and user differential range error index (UDREI). Otherwise, pages 1 through 6 of subframe 4 do not contain the BDS integrity and differential correction information and the user shall not use these pages and the corresponding bits are reserved.

5.3.3.6 BDS Satellite Identification of Integrity and differential correction information (BDID_i)

The BDS satellite identification of integrity and differential correction information (BDID_i, i=1~63) is in 63 bits to identify BDS satellites for which the integrity and differential information are broadcast. Every bit identifies one satellite. “1” means the integrity and differential correction information for the satellite are broadcast and “0” means not.

BDID_i (i=1~30) are broadcast in subframe 2. BDID_i, (i=31~63) are broadcast in subframe 4.

BDS Integrity and differential correction information are allocated in ascending order of the SV ID.

5.3.3.7 BDS Regional User Range Accuracy Index (RURAI)

Regional user range accuracy (RURA) (i.e., BDS satellite signal integrity
information) is used to describe the satellite signal pseudo-range error in meters. RURA is indicated by the regional user range accuracy index (RURAI). Each RURAI occupies 4 bits, so its effective range is 0 to 15. The update period of RURAI is 18 seconds. Each RURAI broadcasted on the B1I signal indicates the integrity for the B1I signal of a given satellite. The corresponding relationship between RURAI and RURA is shown in Table 5-24.

**Table 5-24 RURAI definitions**

<table>
<thead>

<tr>
<td>15</td>
<td>&gt; 300.0</td>
</tr>
</tbody>
</table>

Regional user range accuracy index (RURAI) is broadcast in pages 1 through 6 of subframe 2, subframe 3, and subframe 4. Thereinto, pages 1 through 6 of subframe 4 are used to broadcast the expanded information.
5.3.3.8 BDS Differential Correction and Differential Correction Integrity Information (Δt, UDREI)

5.3.3.8.1 Equivalent Clock Correction (Δt)

The BDS differential correction information is expressed as the equivalent clock correction (Δt). Each Δt for a given satellite is a signed, two’s complement integer which occupies 13 bits, and its quantitative unit is 0.1 m. The update period of Δt is 18 seconds.

Each Δt broadcasted on the B1I signal indicates the differential correction information for the B1I signal of a given satellite. Δt is not available if the value is -4096. The user shall correct the residual error of the satellite clock offset and ephemeris by adding Δt to the observed pseudorange.

Equivalent clock correction (Δt) is broadcast in pages 1 through 6 of subframe 2, subframe 3, and subframe 4. Thereinto, pages 1 through 6 of subframe 4 are used to broadcast the expanded information.

5.3.3.8.2 User Differential Range Error Index (UDREI)

User differential range error (UDRE) (i.e., BDS differential correction integrity) is used to describe the error of equivalent clock correction in meters. UDRE is indicated by the user differential range error index (UDREI). Each UDREI occupies 4 bits, so its effective range is 0 to 15. The update period of UDREI is 3 seconds. Each UDREI broadcasted on the B1I signal indicates the differential correction integrity for the B1I signal of a given satellite. The corresponding relationship between UDREI and UDRE is shown in Table 5-25.

<table>
<thead>
<tr>
<th>UDREI</th>

<tr>
<td>0</td>
<td>1.0</td>
</tr>
<tr>
<td>1</td>
<td>1.5</td>
</tr>
<tr>
<td>2</td>
<td>2.0</td>
</tr>
</tbody>
</table>
User differential range error index (UDREI) is broadcast in pages 1 through 6 of subframe 2 and subframe 4. Thereinto, pages 1 through 6 of subframe 4 are used to broadcast the expanded information.

### 5.3.3.9 Ionospheric Grid Information (Ion)

The information about each ionospheric grid point (Ion) consists of the vertical delay at grid point (dτ) and its error index (GIVEI), occupying 13 bits altogether. The data arrangement and definitions are as follows.

<table>
<thead>
<tr>
<th>Ion definition parameters</th>
<th>Parameter</th>
<th>No. of bits</th>
<th>τ</th>
<th>GIVEI</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>dτ</td>
<td>9</td>
<td></td>
<td>4</td>
</tr>
</tbody>
</table>

The ionospheric grid covers 70 to 145 degrees east longitude and 7.5 to 55 degrees north latitude. This area is divided into 320 grids of 5×2.5 degrees. The definition of ionospheric grid point (IGP) numbers less than or equal to 160 is listed in Table 5-27-1. Pages 1 through 13 broadcast ionospheric grid correction information according to this table.
The definition of ionospheric grid point (IGP) numbers

\[ \text{L} = 70 + \text{INT}((\text{IGP} - 1)/10) \times 5 \]

\[ \text{B} = 5 + (\text{IGP} - \text{INT}((\text{IGP} - 1)/10) \times 10) \times 5 \]

where, INT(*) refers to round down.

The definition of ionospheric grid point (IGP) numbers more than 160 is shown in Table 5-27-2. Pages 60 through 73 broadcast grid ionospheric correction information according to this table.

When IGP \( \leq 160 \), the corresponding longitudes and latitudes are:

\[ \text{L} = 70 + \text{INT}((\text{IGP} - 1)/10) \times 5 \]

\[ \text{B} = 5 + (\text{IGP} - \text{INT}((\text{IGP} - 1)/10) \times 10) \times 5 \]
When IGP > 160, the corresponding longitudes and latitudes are:

\[ L = 70 + \text{INT}((\text{IGP} - 161)/10) \times 5 \]

\[ B = 2.5 + (\text{IGP} - 160 - \text{INT}((\text{IGP} - 161)/10) \times 10) \times 5 \]

where, INT(*) refers to round down.

**5.3.3.9.1 Vertical Delay at Ionospheric Grid Points (\(d\tau\))**

\(d\tau_i\) is the vertical ionosphere delay on B1I signal at the \(i^{th}\) grid point, expressed in scale factor of 0.125 and with unit of meters. The effective range of \(d\tau_i\) is between 0 to 63.625 meters. IGP is not monitored when the \(d\tau_i\) is 111111110 (=63.750meters) and vertical ionosphere delay is not available when the \(d\tau_i\) is 111111111 (=63.875meters).

Making use of the ionospheric correction at grid points, the users compute the ionospheric correction for the intersection point of ionosphere and direction from user to observed satellite by interpolation and add it to the observed pseudo-range. The reference altitude of ionosphere is 375 km.

**5.3.3.9.2 Grid Ionospheric Vertical Error Index (GIVEI)**

The grid ionosphere vertical error (GIVE) describes the delay correction accuracy at ionosphere grid points and is indicated with GIVEI. See Table 5-28 for the relationship between GIVEI and GIVE.

### 5.3.3.9.3 Suggestions on User Grid Ionospheric Correction Algorithm

The user can select effective data of the grid points adjacent to or nearby the observed intersection point with $d\tau_i$ and GIVEI to design the model and compute the delay correction for ionospheric pierce point (IPP) by interpolation. The guiding fitting algorithm for user grid ionospheric correction is given as follows:

#### Figure 5-19 User IPP and Grid Points

Figure 5-19 illustrates the user IPP and its surrounding grid points. IPP, represented with geographic latitudes and longitudes as $(\phi_p, \lambda_p)$, is the geographic location where the line-of-sight between the user and the satellite intersects with the ionospheric layer. The positions of the four surrounding grid points are represented with $(\phi_i, \lambda_i, i=1\sim4)$ and the vertical ionospheric delays on the grid points are represented with $\text{VTEC}_i(i=1\sim4)$ respectively. And $\omega_i(i=1\sim4)$ shows the distance weight between IPP and the four grid points.

As long as there are at least three grid points surrounding the user IPP are
available and effective, the IPP ionospheric delay can be calculated from the vertical ionospheric delay of these effective grid points through the bilinear interpolation algorithm.

\[ \text{Ionodelay}_p = \frac{\sum_{i=1}^{4} \omega_i \cdot \text{VTEC}_i}{\sum_{i=1}^{4} \omega_i} \]

where, \( x_p = \frac{\lambda_p - \lambda_1}{\lambda_2 - \lambda_1}, \ y_p = \frac{\phi_p - \phi_1}{\phi_4 - \phi_1} \),

\( \omega_1 = (1 - x_p) \cdot (1 - y_p), \ \omega_2 = x_p \cdot (1 - y_p), \ \omega_3 = x_p \cdot y_p, \ \omega_4 = (1 - x_p) \cdot y_p. \)

If any grid point of this observation epoch is marked as ineffective, its weight is zero.
